

# VORICONAZOLE MYLAN

## Voriconazole for Injection

200 mg/vial

### PRODUCT DESCRIPTION

White lyophilized powder or cake.

### COMPOSITION

Each vial contains 200 mg of Voriconazole.

Other excipients:

Sulbutoyl-ether- $\beta$ -Cyclodextrin Sodium and Water for Injection

### PHARMACOLOGY

#### Pharmacodynamic properties

##### Mechanism of Action

Voriconazole is a triazole antifungal agent. The primary mode of action of voriconazole is the inhibition of fungal cytochrome P-450-mediated 14  $\alpha$ -lanosterol demethylation, an essential step in fungal ergosterol biosynthesis. The accumulation of 14  $\alpha$ -methyl sterols correlates with the subsequent loss of ergosterol in the fungal cell membrane and may be responsible for the antifungal activity of voriconazole. Voriconazole has been shown to be more selective for fungal cytochrome P-450 enzymes than for various mammalian cytochrome P-450 enzyme systems.

##### Pharmacokinetic/Pharmacodynamic relationship

In 10 therapeutic studies, the median for the average and maximum plasma concentrations in individual subjects across the studies was 2,425 ng/mL (inter-quartile range 1193 to 4,380 ng/mL) and 3,742 ng/mL (inter-quartile range 2,027 to 6,302 ng/mL), respectively. A positive association between mean, maximum or minimum plasma voriconazole concentration and efficacy in therapeutic studies was not found.

Pharmacokinetic-pharmacodynamic analyses of clinical trial data identified positive associations between plasma voriconazole concentrations and both liver function test abnormalities and visual disturbances.

##### Microbiology

*In vitro*, voriconazole displays broad-spectrum antifungal activity with antifungal potency against *Candida* species (including fluconazole resistant *C. krusei* and resistant strains of *C. glabrata* and *C. albicans*) and antifungal activity against all *Aspergillus* species tested. In addition voriconazole shows *in vitro* fungicidal activity against emerging fungal pathogens, including those such as *Scedosporium* or *Fusarium* which have limited susceptibility to existing antifungal agents.

Clinical efficacy (with partial or complete response, see below under Clinical Experience) has been demonstrated for *Aspergillus* spp., including *A. flavus*, *A. fumigatus*, *A. terreus*, *A. niger*, *A. nidulans*, *Candida* spp., including *C. albicans*, *C. glabrata*, *C. krusei*, *C. parapsilosis* and *C. tropicalis* and limited numbers of *C. dubliniensis*, *C. inconspicua*, and *C. guilliermondii*, *Scedosporium* spp., including *S. apiospermum*, *S. prolificans* and *Fusarium* spp.

Other treated fungal infections (with often partial or complete response) included isolated cases of *Alternaria* spp., *Blastomyces dermatitidis*, *Blastoschizomyces capitatus*, *Cladosporium* spp., *Coccidioides immitis*, *Candidobolus coronatus*, *Cryptococcus neoformans*, *Exserohilum rostratum*, *Exophiala spinifera*, *Fonsecaea pedrosoi*, *Madurella mycetomatis*, *Paeclomyces lilacinus*, *Penicillium* spp., including *P. marneffei*, *Phialophora richardiae*, *Scopulariopsis brevicaulis* and *Trichosporum* spp., including *T. beigeli* infections.

*In vitro* activity against clinical isolates has been observed for *Acremonium* spp., *Alternaria* spp., *Bipolaris* spp., *Cadophiala* spp., *Histioplasma capsulatum*, with most strains being inhibited by concentrations of voriconazole in the range 0.05 to 2 mcg/mL.

*In vitro* activity against the following pathogens has been shown, but the clinical significance is unknown: *Curvularia* spp. and *Sporothrix* spp.

##### Breakpoints

Specimens for fungal culture and other relevant laboratory studies (serology, histopathology) should be obtained prior to therapy to isolate and identify causative organisms. Therapy may be instituted before the results of the cultures and other laboratory studies are known; however, once these results become available, anti-infective therapy should be adjusted accordingly. The species most frequently involved in causing human infections include *C. albicans*, *C. parapsilosis*, *C. tropicalis*, *C. glabrata* and *C. krusei*, all of which usually exhibit minimum inhibitory concentrations (MICs) of less than 1 mg/L for voriconazole.

However, the *in vitro* activity of voriconazole against *Candida* species is not uniform. Specifically, for *C. glabrata*, the MICs of voriconazole for fluconazole-resistant isolates are proportionally higher than are those of fluconazole-susceptible isolates. Therefore, every attempt should be made to identify *Candida* to species level. If antifungal susceptibility testing is available, the MIC results may be interpreted using breakpoint criteria.

##### Clinical and Laboratory Standards Institute (CLSI) Breakpoints

###### Breakpoint criteria established by CLSI

###### Susceptibility Testing Methods

*Aspergillus* species and other filamentous fungi: No interpretive criteria have been established for *Aspergillus* species and other filamentous fungi.

*Candida* species: The interpretive standards for voriconazole against *Candida* species are applicable only to tests performed using Clinical and Laboratory Standards Institute (CLSI) microdilution reference method M27 for MIC read at 48 hours or disk diffusion reference method M44 for zone diameter read at 24 hours. *In vitro* susceptibility testing was performed according to the Clinical Laboratory and Standards Institute (CLSI) methods M38-P for moulds and, M27-A and M44-A for yeasts). Voriconazole breakpoints (MIC and zone diameter) have been established for *Candida* species, but not the filamentous fungi, including *Aspergillus* species.

NOTE: Susceptibility testing by dilution methods requires the use of voriconazole susceptibility powder.

Broth Dilution Techniques: Quantitative methods are used to determine antifungal MICs. These MICs provide estimates of the susceptibility of *Candida* species to antifungal agents. MICs should be determined using a standardized procedure at 48 hours. Standardized procedures are based on a microdilution method (broth) with standardized inoculum concentrations and standardized concentrations of voriconazole powder. The MIC values should be interpreted according to the criteria provided in the table below. Diffusion Techniques: Qualitative methods that require measurement of zone diameters also provide reproducible estimates of the susceptibility of *Candida* species to an antifungal agent. One such standardized procedure requires the use of standardized inoculum concentrations. This procedure uses paper discs impregnated with 1 microgram of voriconazole to test the susceptibility of yeasts to voriconazole. Disc diffusion interpretive criteria are also provided in the table below.

###### Susceptibility Interpretive Criteria for Voriconazole

	Broth Dilution at 48 hours (MIC in $\mu$ g/mL)			Disk Diffusion at 24 hours (Zone diameters in mm)		
	Susceptible (S)	Susceptible-dose dependent (S-DD)	Resistant (R)	Susceptible (S)	Susceptible-dose dependent (S-DD)	Resistant (R)
Voriconazole	$\leq 1.0$	2.0	$\geq 4.0$	$\geq 17$	14-16	$\leq 13$

Note 1: Shown are the breakpoints ( $\mu$ g/mL) for voriconazole against *Candida* species. If MICs are measured using a scale that yields results falling between categories, the next higher category is implied. Thus, an isolate with a voriconazole MIC of 1.5  $\mu$ g/mL would be placed in the S-DD category.

The susceptible category implies that isolates are inhibited by the usually achievable concentrations of antifungal agent tested when the recommended dosage is used for the site of infection. The susceptible-dose dependent category implies that an infection due to the isolate may be appropriately treated in body sites where the drugs are physiologically concentrated or when a high dose of drug is used. The resistant category implies that isolates are not inhibited by the usually achievable concentrations of the agent with normal dosage schedules and clinical efficacy of the agent against the isolate has not been reliably shown in treatment studies.

###### Quality Control

Standardized susceptibility test procedures require the use of quality control organisms to control the technical aspects of the test procedures. Standard voriconazole powder and 1  $\mu$ g discs should provide the following range of values noted in the table below. NOTE: Quality control microorganisms are specific strains of organisms with intrinsic biological properties relating to resistance mechanisms and their genetic expression within fungi; the specific strains used for microbiological control are not clinically significant.

###### Acceptable Quality Control Ranges for Voriconazole to be used in Validation of Susceptibility Test Results

	Broth Dilution (MIC in $\mu$ g/mL)		Disk Diffusion (Zone diameter in mm) @ 24-hour	
	@24-hour	@48-hour	@48-hour	
QC Strain				

<i>Candida parapsilosis</i> ATCC 22019	0.016-0.12	0.03-0.25	28-37
<i>Candida krusei</i> ATCC 6258	0.06-0.5	0.12-1.0	16-25
<i>Candida albicans</i> ATCC 90028	*	*	31-42

\* Quality control ranges have not been established for this strain/antifungal agent combination due to their extensive interlaboratory variation during initial quality control studies.

ATCC is a registered trademark of the American Type Culture Collection.

###### Clinical Experience

Successful outcome in this section is defined as complete or partial response.

##### *Aspergillus* infections – efficacy in aspergillosis patients with poor prognosis

Voriconazole has *in vitro* fungicidal activity against *Aspergillus* spp. The efficacy and survival benefit of voriconazole compared to conventional amphotericin B in the primary treatment of acute invasive aspergillosis was demonstrated in an open, randomised, multicenter study in 227 immunocompromised patients treated for 12 weeks. Voriconazole was administered intravenously with a loading dose of 6 mg/kg every 12 hours for the first 24 hours followed by a maintenance dose of 4 mg/kg every 12 hours for a minimum of seven days. Therapy could then be switched to the oral formulation at a dose of 200 mg every 12 hours. Median duration of IV voriconazole therapy was 10 days (range 2-85 days). After IV voriconazole therapy, the median duration of PO voriconazole therapy was 76 days (range 2-232 days).

A satisfactory global response (complete or partial resolution of all attributable symptoms, signs, radiographic/bronchoscopic abnormalities present at baseline) was seen in 53% of voriconazole-treated patients compared to 31% of patients treated with comparator. The 84-day survival rate for voriconazole was statistically significantly higher than that for the comparator and a clinically and statistically significant benefit was shown in favor of voriconazole for both time to death and time to discontinuation due to toxicity.

This study confirmed findings from an earlier, prospectively designed study where there was a positive outcome in subjects with risk factors for a poor prognosis, including graft versus host disease, and, in particular, cerebral infections (normally associated with almost 100% mortality).

The studies included cerebral, sinus, pulmonary and disseminated aspergillosis in patients with bone marrow and solid organ transplants, hematological malignancies, cancer and AIDS.

##### Serious invasive *Candida* infections – efficacy in non-neutropenic patients

The efficacy of voriconazole compared to the regimen of amphotericin B followed by fluconazole in the primary treatment of candidemia was demonstrated in an open, comparative study. Three hundred and seventy (370) non-neutropenic patients (above 12 years of age) with documented candidemia were included in the study of which 248 were treated with voriconazole. The patient population was seriously ill, with approximately 50 % of subjects in the intensive care unit and 40 % mechanically ventilated at baseline. The median treatment duration was 15 days in both treatment arms. In the primary analysis, successful response as assessed by a Data Review Committee (DRC) blinded to study medication was defined as resolution/improvement in all clinical signs and symptoms of infection with eradication of *Candida* from blood and infected deep tissue sites at 12 weeks after EOT (End of Therapy). In this analysis a successful response was seen in 41% of patients in both treatment arms 12 weeks after EOT (End of Therapy).

Patients who did not have an assessment 12 weeks after EOT were counted as failures. In a secondary analysis, which utilised DRC assessments at the latest evaluable time point (EOT, or 2, 6, or 12 weeks after EOT) voriconazole and the regimen of amphotericin B followed by fluconazole had successful response rates of 65 % and 71 %, respectively.

##### Serious refractory *Candida* infections

The study comprised 55 patients with serious refractory systemic *Candida* infections (including candidemia, disseminated and other invasive candidiasis) where prior antifungal treatment, particularly with fluconazole, had been ineffective. Successful response was seen in 24 patients (15 complete, 9 partial responses). In fluconazole-resistant non-*albicans* species, a successful outcome was seen in 3/3 *C. krusei* (complete responses) and 6/8 *C. glabrata* (5 complete, 1 partial response) infections. The clinical efficacy data were supported by limited susceptibility data.

##### Other serious rare fungal pathogens

Voriconazole was shown to be effective against the following rare fungal pathogens:

*Scedosporium* spp. – Successful response to voriconazole therapy was seen in 16 of 28 patients (55%) with *S. apiospermum* and in 2 of 7 patients (29%) *S. prolificans* infection. In addition, a successful response was seen in patients with mixed organism infections. *Fusarium* spp. Seven of 17 (41%) patients were successfully treated with voriconazole. Of these 7 patients, 3 had eye, 1 had sinus, and 3 had disseminated infection. Four additional patients with fusariosis had an infection caused by several organisms; two of them had a successful outcome.

The majority of patients receiving voriconazole treatment of the above-mentioned rare infections were intolerant of, or refractory to, prior antifungal therapy.

##### Primary Prophylaxis of Invasive Fungal Infections – Efficacy in allogeneic hematopoietic stem cell transplant (HSCT) recipients without prior proven or probable invasive fungal infection (IFI)

Voriconazole was compared to itraconazole as primary prophylaxis in an open-label, comparative, multicenter study of adult and adolescent allogeneic HSCT recipients without prior proven or probable IFI. Success was defined as the ability to continue study drug prophylaxis for 100 days after HSCT (without stopping for >14 days) and survival with no proven or probable IFI for 180 days after HSCT. The modified intent-to-treat (MITT) group included 465 allogeneic HSCT recipients, with myeloablation (58%) or reduced-intensity (42%) conditioning regimens. Prophylaxis with study drug was started immediately after HSCT: 224 received voriconazole and 241 received itraconazole. The median duration of study drug prophylaxis was 96 days for voriconazole and 68 days for itraconazole in the MITT group.

Success rates and other secondary endpoints are presented in the table below:

Study Endpoints	Voriconazole N=224	Itraconazole N=241	Difference in proportions and the 95% confidence interval (CI)	P-Value
Success at day 180*	109 (48.7%)	80 (33.2%)	16.4% (7.7%, 25.1%)**	0.0002**
Success at day 100	121 (54.0%)	96 (39.8%)	15.4% (6.6%, 24.2%)**	0.0005**
Completed at least 100 days of study drug prophylaxis	120 (53.6%)	94 (39.0%)	14.6% (5.6%, 23.5%)	0.0016*
Survived to day 180	184 (82.1%)	197 (81.7%)	0.4% (-6.6%, 7.4%)	0.9107
Developed proven or probable IFI to day 180	3 (1.3%)	5 (2.1%)	-0.7% (-3.1%, 1.6%)	0.5390
Developed proven or probable IFI to day 100	2 (0.9%)	4 (1.7%)	-0.8% (-2.8%, 1.3%)	0.4589
Developed proven or probable IFI while on study drug	0	3 (1.2%)	-1.2% (-2.6%, 0.2%)	0.0813

\* Primary endpoint of the study.

\*\* Difference in proportions, 95% CI and p-values obtained after adjustment for randomization.

Pathogens responsible for breakthrough IFI in voriconazole & itraconazole groups

Voriconazole*	<i>Aspergillus fumigatus</i> , <i>Candida krusei</i> , <i>Candida parapsilosis</i>
Itraconazole**	<i>Aspergillus fumigatus</i> , <i>Aspergillus</i> species

\* Breakthrough IFIs occurred after study drug discontinuation.

\*\* Three out of five cases occurred after study drug discontinuation.

##### Secondary Prophylaxis of IFI – Efficacy in HSCT recipients with prior proven or probable IFI

Voriconazole was investigated as secondary prophylaxis in an open-label, non-comparative, multicenter study of adult allogeneic HSCT recipients with prior proven or probable IFI. The primary endpoint was the rate of occurrence of proven and probable IFI during the first year after HSCT. The MITT group included 40 patients with prior IFI, including 31 with aspergillosis, 5 with candidiasis, and 4 with other IFI. The median duration of study drug prophylaxis was 95.5 days in the MITT group.

Proven or probable IFIs developed in 7.5% (3/40) of patients during the first year after HSCT, including one candidemia, one septicosporiosis (both relapses of prior IFI), and one zygomycosis. The survival rate at Day 180 was 80.0% (32/40) and at 1 year was 70.0% (28/40).

##### Duration of Treatment

Intravenous and oral voriconazole allows flexibility in patient care and the possibility of prolonged treatment where indicated. In clinical trials, 714 patients received voriconazole therapy for greater than 12 weeks, with 155 subjects receiving voriconazole for over 6 months.

##### Clinical Studies in Children

Fifty-three pediatric patients aged 2 to <18 years were treated with voriconazole in two prospective, open-label, non-comparative, multi-center clinical trials. One study enrolled 31 patients with possible, proven or probable invasive aspergillosis (IA), of whom 14 patients had proven or probable IA and were included in the MITT efficacy analyses.

The second study enrolled 22 patients with invasive candidiasis including candidemia (IC), and esophageal candidiasis (EC) requiring either primary or salvage therapy, of whom 17 were included in the MITT efficacy analyses. Of the total of 31 patients included in the MITT analyses, 14 were 2 to <12 years of age (5 patients with IA and 9 with IC or EC) and 17 were 12 to <18 years old (9 patients with IA and 8 with IC or EC). The overall rates of global response were 64.3% (9/14) at 6 weeks for patients with IA, 85.7% (6/7) at EOT for patients with IC and 70% (7/10) at EOT for patients with EC. In subjects with IA, the success rate was 40% (2/5) for patients 2 to <12 years and 77.8% (7/9) for patients 12 to <18 years of age.

##### Clinical Studies Examining QT Interval

A placebo-controlled, randomized, single-dose, crossover study to evaluate the effect on the QT interval of healthy volunteers was conducted with three oral doses of voriconazole and ketconazole. The placebo-adjusted mean maximum increases in QTc from baseline after 800, 1200 and 1600 mg of voriconazole were 5.1, 4.8, and 8.2 msec, respectively and 7.0 msec for ketconazole 800 mg. No subject in any group had an increase in QTc of  $\geq$ 60 msec from baseline. No subject experienced an interval exceeding the potentially clinically relevant threshold of 500 msec.

##### Pharmacokinetic properties

###### General Pharmacokinetic Characteristics

The pharmacokinetics of voriconazole has been characterized in healthy subjects, special populations and patients.

The pharmacokinetics of voriconazole is non-linear due to saturation of its metabolism. Greater than proportional increase in exposure is observed with increasing dose.

###### Voriconazole Pharmacokinetic Parameters in Adults Receiving Dosing Regimens

Geometric mean (CV%)*	6 mg/kg IV (loading dose)	3 mg/kg IV Q12h	4 mg/kg IV Q12h
n	35	23	40
AUC <sub>0-24</sub> ( $\mu$ g h/mL)	13.9 (32)	13.7 (53)	33.9 (54)
C <sub>max</sub> ( $\mu$ g/mL)	3.13 (20)	3.03 (25)	4.77 (36)
C <sub>min</sub> ( $\mu$ g/mL)	--	0.46 (97)	1.73 (74)

\* Parameters were estimated based on non-compartmental analysis from 5 pharmacokinetic studies.

AUC<sub>0-24</sub> = area under the curve over 12-hour dosing interval, C<sub>max</sub> = maximum plasma concentration, C<sub>min</sub> = minimum plasma concentration.

When the recommended intravenous dose regimen is administered, plasma concentrations close to steady state are achieved within the first 24 hours of dosing (e.g., 6 mg/kg IV every 12 hours on day 1 followed by 3 mg/kg IV every 12 hours; Without the loading dose, accumulation occurs during twice daily multiple dosing with steady-state plasma voriconazole concentrations being achieved by day 6 in the majority of subjects.

##### Absorption

Voriconazole is rapidly and almost completely absorbed following oral administration, with maximum plasma concentrations (C<sub>max</sub>) achieved 1 to 2 hours after dosing. The oral bioavailability of voriconazole is estimated to be 96%. Bioequivalence was established between the 200 mg tablet and the 40 mg/mL oral suspension when administered as a 400 mg every 12 hours loading dose followed by a 200 mg every 12 hours maintenance dose. When multiple doses of voriconazole are administered with high fat meals, C<sub>max</sub> and AUC, are reduced by 34% and 24%, respectively, when administered as a tablet and by 58% and 37%, respectively, when administered as the oral suspension.

The absorption of voriconazole is not affected by changes in gastric pH.

##### Distribution

The volume of distribution at steady state for voriconazole is estimated to be 4.6 L/kg, suggesting extensive distribution into tissues.

Plasma protein binding is estimated to be 50%.

Cerebrospinal fluid samples from patients in a compassionate programme showed detectable voriconazole concentrations in all patients.

##### Metabolism

*In vitro* studies showed that voriconazole is metabolized by the hepatic cytochrome P450 isoenzymes, CYP2C19, CYP2C9 and CYP3A4.

The inter-individual variability of voriconazole pharmacokinetics is high.

*In vivo* studies indicated that CYP2C19 plays a key role in the metabolism of voriconazole. This enzyme exhibits genetic polymorphism. For example, 15%-20% of Asian populations may be expected to be poor metabolizers. For Caucasians and Blacks, the prevalence of poor metabolizers is 3%-5%. Studies conducted in Caucasian and Japanese healthy subjects have shown that poor metabolizers have, on average, 4-fold higher voriconazole exposure (AUC) than their homozygous extensive metabolizer counterparts. Subjects who are heterozygous extensive metabolizers have on average 2-fold higher voriconazole exposure than their homozygous extensive metabolizer counterparts.

The major metabolite of voriconazole is the N-oxide, which accounts for 72% of the circulating radiolabelled metabolites in plasma. This metabolite has minimal antifungal activity and does not contribute to the overall efficacy of voriconazole.

##### Excretion

Voriconazole is eliminated via hepatic metabolism with less than 2% of the dose excreted unchanged in the urine. After administration of a radiolabelled dose of voriconazole, approximately 80% of the radioactivity is recovered in the urine after multiple intravenous dosing. The majority (> 94%) of the total radioactivity is excreted in the first 96 hours after intravenous dosing. The terminal half-life of voriconazole depends on dose. Because of non-linear pharmacokinetics, the terminal half-life is not useful in the prediction of the accumulation or elimination of voriconazole.

##### Pharmacokinetics in special patient groups

###### Gender

In an oral multiple dose study C<sub>max</sub> and AUC, for healthy young females were 83% and 113% higher, respectively, than in healthy young males (18-45 years) after tablet dosing. In the same study, no significant differences in C<sub>max</sub> and AUC, were observed between healthy elderly males and healthy elderly females ( $\geq$ 65 years). In a similar study, after dosing with the oral suspension, the mean AUC for healthy young females was 45% higher than in healthy young males, whereas the mean C<sub>min</sub> was comparable between genders. The steady-state trough voriconazole concentrations (C<sub>min</sub>) seen in females were 100% and 91% higher than in males receiving the tablet and the oral suspension, respectively.

In the clinical program, no dosage adjustment was made on the basis of gender. The safety profile and plasma concentrations observed in male and female patients were similar. Therefore, no dosage adjustment based on gender is necessary.

###### Elderly

In an oral multiple dose study C<sub>max</sub> and AUC, in healthy elderly females ( $\geq$ 65 years) were 61% and 86% higher, respectively, than in healthy young males (18-45 years). No significant differences in C<sub>max</sub> and AUC, were observed between healthy elderly females ( $\geq$ 65 years) and healthy young females (18-45 years).

In the therapeutic studies no dosage adjustment was made on the basis of age. A relationship between plasma concentrations and age was observed. However, the safety profile of voriconazole in young and elderly patients was similar and, therefore, no dosage adjustment is necessary for the elderly.

###### Pediatrics

The recommended intravenous dose in pediatric patients is based on a population pharmacokinetic analysis of data pooled from 82 immunocompromised pediatric patients aged 2 to <12 years old who were evaluated in three pharmacokinetic studies (examining single intravenous doses of 3 and 4 mg/kg twice daily, multiple intravenous doses of 3, 4, 6 and 8 mg/kg twice daily, multiple oral suspension doses of 4 and 6 mg/kg twice daily). The majority of patients were on one dose level with a maximum duration of dosing of 30 days. A comparison of the pediatric and adult population pharmacokinetic data indicated that in order to obtain comparable exposures to those obtained in adults following intravenous maintenance doses of 4 mg/kg twice daily, intravenous maintenance doses of 7 mg/kg twice daily are required in pediatric patients. The higher intravenous maintenance dose in pediatric patients relative to adults reflects the higher elimination capacity in pediatric patients due to a greater liver mass to body mass ratio.

In order to obtain comparable exposures to those obtained in adults following intravenous maintenance doses of 3 mg/kg twice daily, intravenous maintenance doses of 4 mg/kg twice daily are required in pediatric patients. Based on the population pharmacokinetic analysis, no loading dose or dosage adjustment according to age is warranted in patients aged 2 to <12 years old.

The recommended oral dose in pediatrics is based on a population pharmacokinetic analysis data obtained from 47 immunocompromised pediatric patients aged 2 to <12 years old who were evaluated in a pharmacokinetic study examining multiple oral suspension doses of 4 to 6 mg/kg twice daily. A comparison of the pediatric and adult population pharmacokinetic data indicated that in order to obtain comparable exposures to those obtained in adults following a maintenance dose of 200 mg twice daily, the same dose of 200 mg of oral solution twice daily is required in pediatric patients, independent of body weight. In pediatric patients there is a general trend towards low bioavailability at lower body weights and high bioavailability at higher body weights (towards the extent demonstrated in adults). The estimated bioavailability in pediatric patients following oral administration (FIS) was 44.6%. Based on the population pharmacokinetic analysis, no dosage adjustment according to age or weight is warranted in patients aged 2 to <12 years old at the 200 mg bid oral solution dosing regimen. A loading dose is not indicated in pediatric patients.

A comparison of the pediatric and adult population pharmacokinetic data indicated that the predicted total exposure (AUC) in children following administration of a 9 mg/kg IV loading dose was comparable to that in adults following a 6 mg/kg IV loading dose. The predicted total exposures in children following IV maintenance doses of 4 and 8 mg/kg twice daily were comparable to those in adults following 3 and 4 mg/kg IV twice daily, respectively. The predicted total exposure in children following an oral maintenance dose of 9 mg/kg (maximum of 350 mg) twice daily was comparable to that in adults following 200 mg oral twice daily. An 8 mg/kg intravenous dose will provide voriconazole exposure approximately 2-fold higher than a 9 mg/kg oral dose.

The higher intravenous maintenance dose in pediatric patients relative to adults reflects the higher elimination capacity in pediatric patients due to a greater liver mass to body mass ratio.

Oral bioavailability may however be limited in pediatric patients with malabsorption and very low body weight for their age. In that case, intravenous voriconazole administration is recommended.

##### Renal Impairment

In a single oral dose (200 mg) study in subjects with normal renal function and mild (creatinine clearance 41-60 mL/min) to severe (creatinine clearance <20 mL/min) renal impairment, the pharmacokinetics of voriconazole were not significantly affected by renal impairment. The plasma protein binding of voriconazole was similar in subjects with different degrees of renal impairment. See dosing and monitoring recommendations under see Section **DOSAGE AND ADMINISTRATION** and **SPECIAL WARNINGS AND PRECAUTIONS FOR USE**.

In patients with moderate to severe renal dysfunction (serum creatinine levels  $\geq$ 220 micromol/L) (2.5 mg/dL), accumulation of the intravenous vehicle, SBEDC, occurs. See Section **DOSAGE AND ADMINISTRATION**.

##### Hepatic Impairment

After a single oral dose (200 mg), AUC was 233% higher in subjects with mild to moderate hepatic cirrhosis (Child-Pugh

multiforme (rare) during treatment with voriconazole.

If patients develop a rash they should be monitored closely and voriconazole discontinued if lesions progress. Patients receiving long-term voriconazole therapy have developed photosensitive skin reactions.

Dermatological adverse reactions potentially related to phototoxicity (pseudoporphyria, cheilitis, and cutaneous lupus erythematosus) are also reported with voriconazole. Sun avoidance and photoprotection are recommended for all patients. If phototoxicity occurs, voriconazole discontinuation and dermatological evaluation should be considered.

#### Liver Function Tests

The overall incidence of transaminase increases >3 x ULN (not necessarily comprising an adverse event) in the voriconazole clinical program was 18.0% (191/1,768) in adults and 25.8% (73/283) in pediatric subjects who received voriconazole for pooled therapeutic and prophylaxis use. Liver function test abnormalities may be associated with higher plasma levels and/or doses. The majority of abnormal liver function tests either resolved during treatment without dose adjustment or following dose adjustment, including discontinuation of therapy.

Voriconazole has been associated with cases of serious hepatic toxicity, in patients with other serious underlying conditions. This includes cases of jaundice, hepatitis and hepatic failure leading to death.

#### Pediatric Use

The safety of voriconazole was investigated in pediatric patients aged 2 to <12 years and 12 to <18 years who received voriconazole for prophylaxis and therapeutic use. The adverse event profile in these pediatric patients was similar to that in adults. A higher frequency of liver enzyme elevations reported as adverse events (14.2% transaminases increased in pediatrics compared to 5.3% in adults) was observed in pediatric patients as compared to adults. The safety of voriconazole was investigated in additional pediatric patients aged 2 to <12 years who were observed in compassionate use programs (pediatric patients). The adverse event profile in these pediatric patients was similar to that observed in adults.

Post-marketing data suggest there might be a higher occurrence of skin reactions in the pediatric population compared to adults. In patients less than 2 years old who received voriconazole in a compassionate use programme, the following adverse events (or with a relationship to voriconazole could not be excluded) were reported: photosensitivity reaction (1), arrhythmia (1), pancreatitis (1), blood bilirubin increased (1), hepatic enzymes increased (1), rash (1) and papilloedema (1). There have been post-marketing reports of pancreatitis in pediatric patients.

#### Altered Taste Perception

In the combined data from three bioequivalence studies using the powder for oral suspension formulation, treatment related taste perversion was recorded in 114% of subjects.

#### Infection-related Reactions

During infusion of the intravenous formulation of voriconazole in healthy subjects, anaphylactoid-type reactions, including flushing, fever, sweating, tachycardia, chest tightness, dyspnea, faintness, nurlitis and rash have occurred. Symptoms appeared immediately upon initiating the infusion.

### SPECIAL WARNINGS AND PRECAUTIONS FOR USE

**Hypersensitivity:** Caution should be used in prescribing voriconazole to patients with hypersensitivity to other azoles.

**Infection-related reactions:** Infection-related reactions, predominantly flushing and rashes have been observed during administration of the intravenous formulation of voriconazole. Depending on the severity of symptoms, consideration should be given to stopping treatment. (see Section **SIDE EFFECTS**)

**Cardiac adverse events:** Some azoles, including voriconazole, have been associated with QT interval prolongation on the electrocardiogram. During clinical development and post-marketing surveillance, there have been rare cases of *torsades de pointes* in patients taking voriconazole who had risk factors, such as history of cardiotoxic chemotherapy, cardiomyopathy, hypokalaemia and concomitant medications that may have been contributory. Voriconazole should be administered with caution to patients with potentially proarrhythmic conditions, such as

- Congenital or acquired QT-prolongation
- Cardiomyopathy, in particular when heart failure is present
- Sinus bradycardia
- Existing symptomatic arrhythmias
- Concomitant medication that is known to prolong QT interval (see Section **DRUG INTERACTIONS**)

Electrolyte disturbances such as hypokalaemia, hypomagnesaemia and hypocalcaemia should be monitored and corrected, if necessary, prior to initiation of and during voriconazole therapy (see Section **DOSSAGE AND ADMINISTRATION**).

A study has been conducted in healthy volunteers which examined the effect on QT interval of single doses of voriconazole up to 4 times the usual daily dose. No subject experienced an interval exceeding the potentially clinically relevant threshold of 500 msec (see Section **Pharmacodynamic properties**).

**Hepatic toxicity:** In clinical trials, there have cases of serious hepatic reactions during treatment with voriconazole (including clinical hepatitis, cholestasis and fulminant hepatic failure, including fatalities). Instances of hepatic reactions were noted to occur primarily in patients with serious underlying medical conditions (predominantly hematological malignancy). Transient hepatic reactions, including hepatitis and jaundice, have occurred among patients with no other identifiable risk factors. Liver dysfunction has usually been reversible on discontinuation of therapy.

**Monitoring of hepatic function:** Patients receiving voriconazole must be carefully monitored for hepatic toxicity. Clinical management should include laboratory evaluation of hepatic function (particularly liver function tests and bilirubin) at the initiation of treatment with voriconazole and at least weekly for the first month of treatment. If treatment is continued, monitoring frequency can be reduced to monthly if there are no changes in the liver function tests.

If the liver function tests become markedly elevated, voriconazole should be discontinued, unless the medical judgment of the risk-benefit of the treatment for the patient justifies continued use (see Section **DOSSAGE AND ADMINISTRATION**).

**Visual adverse events:** There have been post-marketing reports of prolonged visual adverse events, including optic neuritis and papilledema. These events occurred primarily in severely ill patients who had underlying conditions and/or concomitant medications which may have caused or contributed to events (see Section **SIDE EFFECTS**).

**Renal adverse events:** Acute renal failure has been observed in severely ill patients undergoing treatment with voriconazole. Patients being treated with voriconazole are likely to be treated concomitantly with nephrotoxic medications and have concurrent conditions that may result in decreased renal function.

**Monitoring of renal function:** Patients should be monitored for the development of abnormal renal function. This should include laboratory evaluation, particularly serum creatinine (see Section **DOSSAGE AND ADMINISTRATION**).

**Monitoring of pancreatic function:** Adults and children with risk factors for acute pancreatitis (e.g., recent chemotherapy, hematopoietic stem cell transplantation [HSCT]), should be monitored closely for development of pancreatitis during voriconazole treatment. Monitoring of serum amylase or lipase may be considered in this clinical situation.

**Dermatological adverse events:** During treatment with voriconazole, patients have developed severe cutaneous adverse reactions (SCARs), such as Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), and drug reaction with eosinophilia and systemic symptoms (DRESS) which can be life-threatening or fatal (see Section **SIDE EFFECTS**). If a patient develops a severe cutaneous adverse reaction voriconazole should be discontinued.

In addition voriconazole has been associated with photosensitivity skin reaction. An increased risk of skin toxicity with concomitant use of methotrexate, a drug associated with ultraviolet (UV) reactivation has been observed. There is a potential for this risk to be observed with other drugs associated with UV reactivation. It is recommended that patients, including children avoid exposure to direct sunlight during voriconazole treatment and use measures such as protective clothing and sunscreen with high sun protection factor (SPF).

**Adrenal events:** Reversible cases of adrenal insufficiency have been reported in patients receiving azoles, including voriconazole. Adrenal insufficiency has been reported in patients receiving azoles with or without concomitant corticosteroids. In patients receiving azoles without corticosteroids, adrenal insufficiency is related to direct inhibition of steroidogenesis by azoles. In patients taking corticosteroids, voriconazole associated CYP3A4 inhibition of their metabolism may lead to corticosteroid excess and adrenal suppression (see Section **DRUG INTERACTIONS**). Cushing's syndrome with and without subsequent adrenal insufficiency has also been reported in patients receiving voriconazole concomitantly with corticosteroids.

**Patients on long-term treatment** with voriconazole and corticosteroids (including inhaled corticosteroids e.g., budesonide) should be carefully monitored for adrenal cortex dysfunction both during treatment and when voriconazole is discontinued (see Section **DRUG INTERACTIONS**). Patients should be instructed to seek immediate medical care if they develop signs and symptoms of Cushing's syndrome or adrenal insufficiency.

Fluconazole (CYP2C9, CYP2C19 and CYP3A4 inhibitor): Co-administration of oral voriconazole and oral fluconazole resulted in a significant increase in  $C_{max}$  and AUC<sub>0-24</sub> of voriconazole in healthy subjects. The reduced dose and/or frequency of voriconazole and fluconazole that would eliminate this effect have not been established. Monitoring for voriconazole associated adverse events is recommended if voriconazole is used sequentially after fluconazole (see Section **DRUG INTERACTIONS**).

Glasdegib (CYP3A4 substrate): Co-administration of voriconazole is expected to increase glasdegib plasma concentrations and increase the risk of QTc prolongation (see Section **DRUG INTERACTIONS**). If concomitant use cannot be avoided, frequent ECG monitoring is recommended.

#### Long-term treatment

The following severe adverse events have been reported in relation with long-term voriconazole treatment:

Squamous cell carcinoma of the skin (SCC): In patients with photosensitivity skin reactions and additional risk factors, squamous cell carcinoma of the skin and melanoma have been reported during long-term therapy. If phototoxic reactions occur, multidisciplinary advice should be sought and the patient should be referred to a dermatologist. Voriconazole discontinuation should be considered. Dermatologic evaluation should be performed on a systematic and regular basis, whenever voriconazole is continued despite the occurrence of phototoxicity-related lesions, to allow early detection and management of premalignant lesions.

If a patient develops a skin lesion consistent with premalignant skin lesions, squamous cell carcinoma or melanoma, voriconazole discontinuation should be considered.

Non-infectious perioritis: Perioritis has been reported in transplant patients during long-term voriconazole therapy. If a patient develops skeletal pain and radiologic findings compatible with perioritis, voriconazole should be discontinued.

**Pediatric use:** Safety and effectiveness in pediatric subjects below the age of 2 years has not been established. Voriconazole is indicated for pediatric patients aged two years or older. A higher frequency of liver enzyme elevations was observed in the pediatric population. Hepatic function should be monitored in both children and adults.

The frequency of phototoxicity reactions is higher in the pediatric population. As an evolution towards SCC has been reported, stringent measures for the photoprotection are warranted in this population of patients. In children experiencing phototoxic injuries such as lentiginos or ephelides, sun avoidance and dermatologic follow-up are recommended even after treatment discontinuation. Dermatologic evaluation should be performed on a systematic and regular basis, whenever voriconazole is continued despite the occurrence of phototoxicity-related lesions, to allow early detection and management of premalignant lesions.

**Everolimus** (CYP3A4 substrate, P-gp substrate): Co-administration of voriconazole with everolimus is not recommended because voriconazole is expected to significantly increase everolimus concentrations. Currently there are insufficient data to allow dosing recommendations in this situation (see Section **DRUG INTERACTIONS**).

**Efavirenz** (CYP450 inducer, CYP3A4 inhibitor and substrate): When voriconazole is co-administered with efavirenz, the dose of voriconazole should be increased to 400 mg every 12 hours and that of efavirenz should be decreased to 300 mg every 24 hours (see Sections **DOSSAGE AND ADMINISTRATION**, **CONTRAINDICATIONS** AND **DRUG INTERACTIONS**).

**Phenytoin** (CYP2C9 substrate and potent CYP450 inducer): Careful monitoring of phenytoin levels is recommended when phenytoin is co-administered with voriconazole. Concomitant use of voriconazole and phenytoin should be avoided unless the benefit outweighs the risk (see Section **DRUG INTERACTIONS**).

**Ritonavir** (potent CYP450 inducer, CYP3A4 inhibitor and substrate): Co-administration of voriconazole and low dose ritonavir (100 mg twice daily) should be avoided unless an assessment of the benefit/risk justifies the use of voriconazole.

**Methadone** (CYP3A4 substrate): Frequent monitoring for adverse events and toxicity related to methadone, including QT prolongation, is recommended when co-administered with voriconazole since methadone levels increased following co-administration of voriconazole. Dose reduction of methadone may be needed.

**Short-acting opiates** (CYP3A4 substrate): Reduction in the dose of alfentanil, fentanyl and other short-acting opiates similar in structure to alfentanil and metabolized by CYP3A4 (e.g., sufentanil) should be considered when co-administered with voriconazole. As the half-life of alfentanil is prolonged in a 4-fold manner when alfentanil is co-administered with voriconazole and in an independent published study, concomitant use of voriconazole with fentanyl resulted in an increase in the mean AUC<sub>0-24</sub> of fentanyl by 1.4-fold, frequent monitoring for opiate-associated adverse events (including a longer respiratory monitoring period) may be necessary.

**Long-acting opiates** (CYP3A4 substrate): Reduction in the dose of oxycodone and other long-acting opiates metabolized by CYP3A4 (e.g., hydrocodone) should be considered when co-administered with voriconazole. Frequent monitoring for opiate-associated adverse events may be necessary.

**Visual disturbances:** The effect of Voriconazole for Injection on visual function is not known if treatment continues beyond 28 days. If treatment continues beyond 28 days, visual function including visual acuity, visual field and colour perception should be monitored.

**Cyclosporine and tacrolimus** (CYP3A4 substrates): Clinically significant drug interactions with voriconazole may occur in patients who are receiving treatment with cyclosporine or tacrolimus (see Section **DRUG INTERACTIONS**).

### CONTRAINDICATIONS

Voriconazole is contraindicated in patients with known hypersensitivity to voriconazole or to any of the excipients.

Co-administration of the CYP3A4 substrates, terfenadine, astemizole, cisapride, pimozide, quinidine or ivabradine with voriconazole is contraindicated since increased plasma concentrations of these medicinal products can lead to QTc prolongation and rare occurrences of torsades de pointes (see Section **DRUG INTERACTIONS**).

Co-administration of voriconazole with naltrexol is contraindicated because voriconazole may significantly increase plasma concentrations of naltrexol which may precipitate opioid withdrawal symptoms (see Section **DRUG INTERACTIONS**).

Co-administration of voriconazole with telaparin is contraindicated because voriconazole may significantly increase plasma concentrations of telaparin (see Section **DRUG INTERACTIONS**).

Co-administration of voriconazole with venetoclax is contraindicated at initiation and during the venetoclax dose titration phase since voriconazole is likely to significantly increase plasma concentrations of venetoclax and increase risk of tumour lysis syndrome (see Section **DRUG INTERACTIONS**).

Co-administration of voriconazole with lurasidone is contraindicated since it may result in significant increases in lurasidone exposure and the potential for serious adverse reactions (see Section **DRUG INTERACTIONS**).

Co-administration of voriconazole and sirolimus is contraindicated, since voriconazole has been shown to significantly increase plasma concentrations of sirolimus in healthy subjects (see Section **DRUG INTERACTIONS**).

Co-administration of voriconazole with rifabutin, rifampicin, carbamazepine and long-acting barbiturates (e.g., phenobarbital) is contraindicated since these medicinal products are likely to decrease plasma voriconazole concentrations significantly. (see Section **DRUG INTERACTIONS**).

Co-administration of standard doses of voriconazole with efavirenz doses of 400 mg QD or higher is contraindicated because efavirenz significantly decreases plasma voriconazole concentrations in healthy subjects at this dose. Voriconazole also significantly increases efavirenz plasma concentrations (see Section **DRUG INTERACTIONS**, for lower doses see Section **SPECIAL WARNINGS AND PRECAUTIONS FOR USE**).

Co-administration of ergot alkaloids (ergotamine, dihydroergotamine), which are CYP3A4 substrates, is contraindicated since increased plasma concentrations of these medicinal products can lead to ergotism.

Co-administration of voriconazole with high-dose ritonavir (400 mg and above twice daily) is contraindicated because ritonavir significantly decreases plasma voriconazole concentrations in healthy subjects at this (see Section **DRUG INTERACTIONS**, for lower doses see Section **SPECIAL WARNINGS AND PRECAUTIONS FOR USE**).

Co-administration of voriconazole with St. John's Wort is contraindicated (see Section **DRUG INTERACTIONS**).

### DRUG INTERACTIONS

Voriconazole is metabolised by, and inhibits the activity of, cytochrome P450 isoenzymes, CYP2C19, CYP2C9, and CYP3A4. Inhibitors or inducers of these isoenzymes may increase or decrease voriconazole plasma concentrations, respectively, and there is potential for voriconazole to increase the plasma concentrations of substances metabolised by these CYP450 isoenzymes, in particular for substances metabolised by CYP3A4 since voriconazole is a strong CYP3A4 inhibitor though the increase in AUC is substrate dependent (see Interaction table below). Unless otherwise specified, drug interaction studies have been performed in healthy adult male subjects using multiple dosing to steady state with oral voriconazole at 200 mg twice daily (BD). These results are relevant to other populations and routes of administration.

Voriconazole should be administered with caution in patients with concomitant medication that is known to prolong QT interval. When there is also a potential for voriconazole to increase the plasma concentrations of substances metabolised by CYP3A4 isoenzymes (certain antiarrhythmics, quinidine, cisapride, pimozide and ivabradine) coadministration is contraindicated (see below and Section **CONTRAINDICATIONS**).

#### Interaction table

Interactions between voriconazole and other medicinal products are listed in the table below (once daily as "QD", twice daily as "BD", three times daily as "TID" and not determined as "ND"). The direction of the arrow for each pharmacokinetic parameter is based on the 90% confidence interval of the geometric mean ratio being within (++) , below (-) or above (+) the 80%-125% range. The asterisk (\*) indicates a two-way interaction. AUC<sub>0-24</sub> and AUC<sub>0-12</sub> represent area under the curve over a dosing interval, from time zero to the time with detectable measurement and from time zero to infinity, respectively.

The interactions in the table are presented in the following order: contraindications, those requiring dose adjustment and careful clinical and/or biological monitoring, and finally those that have no significant pharmacokinetic interaction but may be of clinical interest in this therapeutic field.

Medicinal product [mechanism of interaction]	Interaction Geometric mean changes (%)	Recommendations concerning co-administration
Astemizole, cisapride, pimozide, quinidine, terfenadine and ivabradine [CYP3A4 substrates]	Although not studied, increased plasma concentrations of these medicinal products can lead to QTc prolongation and rare occurrences of <i>torsades de pointes</i> [CYP3A4 substrates]	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Carbamazepine and long-acting barbiturates (e.g., phenobarbital, mephobarbital) [potent CYP450 inducers]	Although not studied, carbamazepine and long-acting barbiturates are likely to significantly decrease plasma voriconazole concentrations.	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Efavirenz (a non-nucleoside reverse transcriptase inhibitor) [CYP450 inducer, CYP3A4 inhibitor and substrate]	Use of standard doses of voriconazole with efavirenz doses of 400 mg QD or higher is <b>contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).	
Flavirenz 400 mg QD, co-administered with voriconazole 200 mg BID	Flavirenz $C_{max}$ ↑ 38% Flavirenz AUC <sub>0-24</sub> ↑ 44% Voriconazole $C_{max}$ ↓ 61% Voriconazole AUC <sub>0-24</sub> ↓ 77%	Voriconazole may be co-administered with efavirenz if the voriconazole maintenance dose is increased to 400 mg BID and the efavirenz dose is decreased to 300 mg QD. When voriconazole treatment is stopped, the initial dose of efavirenz should be restored (see Section <b>DOSSAGE AND ADMINISTRATION</b> ).
Flavirenz 300 mg QD, co-administered with voriconazole 400 mg BID*	Compared to efavirenz 600 mg QD, Flavirenz $C_{max}$ ↔ Compared to voriconazole 200 mg BID, Voriconazole $C_{max}$ ↓ 23% Voriconazole AUC <sub>0-24</sub> ↓ 7%	
Ergot alkaloids (e.g., ergotamine and dihydroergotamine) [CYP3A4 substrates]	Although not studied, voriconazole is likely to increase the plasma concentrations of ergot alkaloids and lead to ergotism.	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Lurasidone [CYP3A4 substrate]	Although not studied, voriconazole is likely to significantly increase the plasma concentrations of lurasidone.	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Naloxegol [CYP3A4 substrate]	Although not studied, voriconazole is likely to increase the plasma concentrations of naloxegol.	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Rifabutin [potent CYP450 inducer]	Voriconazole $C_{max}$ ↓ 69% Voriconazole AUC <sub>0-24</sub> ↓ 78%	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
300 mg QD	Compared to voriconazole 200 mg BID, Voriconazole $C_{max}$ ↓ 4% Voriconazole AUC <sub>0-24</sub> ↓ 32%	
300 mg QD (co-administered with voriconazole 350 mg BID)*	Rifabutin $C_{max}$ ↑ 195% Rifabutin AUC <sub>0-24</sub> ↑ 331% Compared to voriconazole 200 mg BID, Voriconazole $C_{max}$ ↑ 104% Voriconazole AUC <sub>0-24</sub> ↑ 87%	
300 mg QD (co-administered with voriconazole 400 mg BID)*		

Rifampicin (600 mg QD) [potent CYP450 inducer]	Voriconazole $C_{max}$ ↓ 93% Voriconazole AUC <sub>0-24</sub> ↓ 96%	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Ritonavir (protease inhibitor) [potent CYP450 inducer, CYP3A4 inhibitor and substrate]	Ritonavir $C_{max}$ and AUC <sub>0-24</sub> ↔ Voriconazole $C_{max}$ ↓ 68% Voriconazole AUC <sub>0-24</sub> ↓ 82%	Co-administration of voriconazole and high doses of ritonavir (400 mg and higher BID) is <b>contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
High dose (400 mg BID)		Co-administration of voriconazole and low dose ritonavir (100 mg BID) should be avoided, unless an assessment of the benefit/risk to the patient justifies the use of voriconazole.
Low dose (100 mg BID) *	Ritonavir $C_{max}$ ↓ 25% Ritonavir AUC <sub>0-24</sub> ↓ 24% Voriconazole $C_{max}$ ↓ 24% Voriconazole AUC <sub>0-24</sub> ↓ 39%	
St. John's Wort [CYP450 inducer, P-gp inducer]	In an independent published study, Voriconazole $C_{max}$ ↓ 59%	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
300 mg TID (co-administered with voriconazole 400 mg single dose)		
Telaparin [CYP3A4 substrate]	Although not studied, voriconazole is likely to significantly increase the plasma concentrations of telaparin.	<b>Contraindicated</b> (see Section <b>CONTRAINDICATIONS</b> ).
Venetoclax [CYP3A4 substrate]	Although not studied, voriconazole is likely to significantly increase the plasma concentrations of venetoclax.	Concomitant administration of voriconazole is <b>contraindicated</b> at initiation and during venetoclax dose titration phase (see Section <b>CONTRAINDICATIONS</b> ). Dose reduction of venetoclax is required as instructed in venetoclax prescribing information during steady daily dosing; close monitoring for signs of toxicity is recommended.
Fluconazole (200 mg QD) [CYP2C9, CYP2C19 and CYP3A4 inhibitor]	Voriconazole $C_{max}$ ↑ 57% Voriconazole AUC <sub>0-24</sub> ↑ 79% Fluconazole $C_{max}$ ND Fluconazole AUC <sub>0-24</sub> ND	The reduced dose and/or frequency of voriconazole and fluconazole that would eliminate this effect have not been established. Monitoring for voriconazole-associated adverse events is recommended if voriconazole is used sequentially after fluconazole.
Phenytoin [CYP2C9 substrate and potent CYP450 inducer]	Voriconazole $C_{max}$ ↓ 49% Voriconazole AUC <sub>0-24</sub> ↓ 69%	Phenytoin may be co-administered with voriconazole if the maintenance dose of voriconazole is increased to 5 mg/kg IV BID or from 200 to 400 mg oral BID (100 mg to 200 mg oral BID in patients less than 40 kg) (see Section <b>DOSSAGE AND ADMINISTRATION</b> ).
300 mg QD		Benefit outweighs the risk. Careful monitoring of phenytoin plasma levels is recommended.
300 mg QD (co-administered with voriconazole 400 mg BID)*	Phenytoin $C_{max}$ ↑ 67% Phenytoin AUC <sub>0-24</sub> ↑ 81% Compared to voriconazole 200 mg BID, Voriconazole $C_{max}$ ↑ 34% Voriconazole AUC <sub>0-24</sub> ↑ 39%	
Lelemtovir [CYP2C9 and CYP2C19 inducer]	Voriconazole $C_{max}$ ↓ 39% Voriconazole AUC <sub>0-24</sub> ↓ 44% Voriconazole C12 ↓ 51%	If concomitant administration of voriconazole with lelemtovir cannot be avoided, monitor for loss of voriconazole effectiveness.
Lemborexant [CYP3A4 substrate]	Although not studied, voriconazole is likely to increase the plasma concentrations of lemborexant.	Concomitant use of voriconazole and lemborexant should be avoided.
Glasdegib [CYP3A4 substrate]	Although not studied, voriconazole is likely to increase the plasma concentrations of glasdegib and increase risk of QTc prolongation.	If concomitant use cannot be avoided, frequent ECG monitoring is recommended.
Tyrosine kinase inhibitors (e.g., axitinib, besutimib, cabozantinib, ceritinib, cobimetinib, dabrafenib, dasatinib, nilotinib, sunitinib, tucatinib, vandetanib, vortioxetine, vandetanib, vandetanib, vandetanib) [CYP3A4 substrates]	Although not studied, voriconazole may increase plasma concentrations of tyrosine kinase inhibitors metabolised by CYP3A4.	If concomitant use cannot be avoided, dose reduction of the tyrosine kinase inhibitor is recommended.
Anticoagulants Warfarin (30 mg single dose, co-administered with 300 mg BID voriconazole) [CYP2C9 substrate]	Maximum increase in prothrombin time was approximately 2-fold.	Close monitoring of prothrombin time or other suitable anticoagulation tests is recommended, and the dose of anticoagulants should be adjusted accordingly.
Other oral coumarins (e.g., phenprocoumon, acenocoumarol) [CYP2C9 and CYP3A4 substrates]	Although not studied, voriconazole may increase the plasma concentrations of coumarins that may cause an increase in prothrombin time.	
Ivacaftor [CYP3A4 substrate]	Although not studied, voriconazole is likely to increase the plasma concentrations of ivacaftor with risk of increased adverse effects.	Dose reduction of ivacaftor is recommended.
Ezopiclone [CYP3A4 substrate]	Although not studied, voriconazole is likely to increase the plasma concentrations and sedative effect of ezopiclone.	Dose reduction of ezopiclone is recommended.
Benzodiazepines [CYP3A4 substrates] Midazolam (0.05 mg/kg IV single dose) Midazolam (7.5 mg oral single dose)	In an independent published study, Midazolam $C_{max}$ ↑ 3.8-fold Midazolam AUC <sub>0-24</sub> ↑ 10.3-fold	Dose reduction of benzodiazepines should be considered.
Other benzodiazepines (e.g., triazolam, alprazolam)	Although not studied, voriconazole is likely to increase the plasma concentrations of other benzodiazepines that are metabolised by CYP3A4 and lead to a prolonged sedative effect.	
Immunosuppressants [CYP3A4 substrates]	In an independent published study, Everolimus $C_{max}$ ↓ 6.6-fold Sirolimus AUC <sub>0-24</sub> ↑ 11-fold	Co-administration of voriconazole and sirolimus is <b>contraindicated</b> . (see Section <b>CONTRAINDICATIONS</b> ).
Sirolimus (2 mg single dose)		Co-administration of voriconazole and everolimus is not recommended because voriconazole is expected to significantly increase everolimus concentrations (see Section <b>SPECIAL WARNINGS AND PRECAUTIONS FOR USE</b> ).
Everolimus [also P-gp substrate]	Although not studied, voriconazole is likely to significantly increase the plasma concentrations of everolimus	
Ciclosporin (in stable renal transplant recipients receiving chronic ciclosporin therapy)	Ciclosporin $C_{max}$ ↑ 13% Ciclosporin AUC <sub>0-24</sub> ↑ 70%	When initiating voriconazole in patients already on ciclosporin it is recommended that the ciclosporin dose be halved and ciclosporin levels carefully monitored. Increased ciclosporin levels have been associated with nephrotoxicity. When voriconazole is discontinued, ciclosporin levels must be carefully monitored and the dose increased, as necessary.
Tacrolimus (0.1 mg/kg single dose)	Tacrolimus $C_{max}$ ↑ 117% Tacrolimus AUC <sub>0-24</sub> ↑ 221%	When initiating voriconazole in patients already on tacrolimus, it is recommended that the tacrolimus dose be reduced to a third of the original dose and tacrolimus level carefully monitored. Increased tacrolimus levels have been associated with nephrotoxicity. When voriconazole is discontinued, tacrolimus levels must be carefully monitored and the dose increased as necessary.

Long Acting Opiates [CYP3A4 substrates] Oxycodone (10 mg single dose)	In an independent published study, Oxycodone $C_{max}$ ↑ 1.7-fold Oxycodone AUC <sub>0-24</sub> ↑ 3.6-fold	Dose reduction in oxycodone and other long-acting opiates metabolized by CYP3A4 (e.g., hydrocodone) should be considered. Frequent monitoring for opiate-associated adverse events may be necessary.
Methadone (32-100 mg QD) [CYP3A4 substrate]	R-methadone (active) $C_{max}$ ↑ 31% R-methadone (active) AUC <sub>0-24</sub> ↑ 47% S-methadone $C_{max}$ ↑ 65% S-methadone AUC <sub>0-24</sub> ↑ 103%	Frequent monitoring for adverse events and toxicity related to methadone, including QT prolongation, is recommended. Dose reduction of methadone may be needed.
Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) [CYP2C9 substrates] Ibuprofen (400 mg single dose)	S-Ibuprofen $C_{max}$ ↓ 20% S-Ibuprofen AUC <sub>0-24</sub> ↓ 100%	Frequent monitoring for adverse events and toxicity related to NSAIDs is recommended. Dose reduction of NSAIDs may be needed.
Diclofenac (50 mg single dose)	Diclofenac $C_{max}$ ↑ 114% Diclofenac AUC <sub>0-24</sub> ↑ 78%	
Omeprazole (40 mg QD)* [CYP2C19 inhibitor, CYP2C19 and CYP3A4 substrate]	Omeprazole $C_{max}$ ↑ 116% Omeprazole AUC <sub>0-24</sub> ↑ 280% Voriconazole $C_{max}$ ↓ 15% Voriconazole AUC <sub>0-24</sub> ↓ 41%	No dose adjustment of voriconazole is recommended.
Other proton pump inhibitors that are CYP2C19 substrates may also be inhibited by voriconazole and may result in increased plasma concentrations of these medicinal products		When initiating voriconazole in patients already receiving omeprazole doses of 40 mg or above, it is recommended that the omeprazole dose be halved.
Oral Contraceptives* [CYP3A4 substrate, CYP2C19 inhibitor] Ethinylestradiol/ethinylestradiol (1 mg/0.035 mg QD)	Ethinylestradiol $C_{max}$ ↑ 36% Ethinylestradiol AUC <sub>0-24</sub> ↑ 61% Norethisterone $C_{max}$ ↑ 15% Norethisterone AUC <sub>0-24</sub> ↑ 53% Voriconazole $C_{max}$ ↑ 14% Voriconazole AUC <sub>0-24</sub> ↑ 46%	Monitoring for adverse events related to oral contraceptives, in addition to those for voriconazole, is recommended.
Short Acting Opiates [CYP3A4 substrates] Alfentanil (20 µg/kg single dose, with concomitant naloxone) Fentanyl (5 µg/kg single dose)	In an independent published study, Alfentanil AUC <sub>0-24</sub> ↑ 6-fold In an independent published study, Fentanyl AUC <sub>0-24</sub> ↑ 1.34-fold	Dose reduction of alfentanil, fentanyl and other short acting opiates similar in structure to alfentanil and metabolised by CYP3A4 (e.g., sufentanil) should be considered. Extended and frequent monitoring for respiratory depression and other opiate-associated adverse events is recommended.
Statins (e.g., lovastatin) [CYP3A4 substrates]	Although not studied, voriconazole is likely to increase the plasma concentrations of statins that are metabolised by CYP3A4 and could lead to rhabdomyolysis.	If concomitant administration of voriconazole with statins metabolised by CYP3A4 cannot be avoided, dose reduction of the statin should be considered.
Sulphonylureas (e.g., tolbutamide, glibenclamide, gliburide) [CYP2C9 substrates]	Although not studied, voriconazole is likely to increase the plasma concentrations of sulphonylureas and cause hypoglycaemia.	Careful monitoring of blood glucose is recommended. Dose reduction of sulphonylureas should be considered.
Vinca Alkaloids (e.g., vincristine and vinblastine) [CYP3A4 substrates]	Although not studied, voriconazole is likely to increase the plasma concentrations of vinca alkaloids and lead to neurotoxicity.	Dose reduction of vinca alkaloids should be considered.
Other HIV Protease Inhibitors (e.g., saquinavir, amprenavir and nelfinavir) [CYP3A4 substrates and inhibitors]	Not studied clinically. <i>In vitro</i> studies show that voriconazole may inhibit the metabolism of HIV protease inhibitors and the metabolism of voriconazole may also be inhibited by HIV protease inhibitors.	Careful monitoring for
